

01-10-2025

dictionary ~

import pandas as pd✓ data = {

"Name": ["Alice", "Peter", "John"],

"Age": [20, 21, 21],

"Salary": [10000, 20000, 100000]}

df = pd.DataFrame(data)

df.head() ✓

df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})

df →

	A	B
0	1	4
1	2	5
2	3	6

	0	1	2
A	1	2	3
B	4	5	6

df.iloc[2, 2] = 100

✓ * if all the columns are numeric

then we can apply ~~sum~~ df.mean()to 5.1

entire null values.

✓ so if there is a string in any one of the columns

✓
* if there is a string in any one of the column
then we need to apply individually Filling

$$\frac{4+5+3}{3} = \frac{12}{3} = \frac{5.33333}{3} \quad \frac{1}{3} (5.33333) = \frac{15}{10} = \frac{9}{10}$$

Recap: creating dataframe from dictionary
adding the column
removing the column
updating the column value
fill null values
sum, mean, fillna("Average")
how do we read iris data
